## Introduction

The Sunscreen Innovation Act was enacted on November 26, 2014, to help speed up the endorsement interaction for UV channels by the US Food and Drug Administration (FDA), given that no new channels had been supported in quite a long while. Almost 5 years after the fact, on February 26, 2019, the FDA delivered a proposed rule in light of the Sunscreen Innovation Act that tended to the grouping and naming of over-the-counter sunscreen items. A part of this FDA proposition is to arrange the 16 sunscreen dynamic fixings (ie, UV channels) recorded in the 1999 FDA last monograph into 3 classes: classification I, by and large perceived as protected and powerful (GRASE); class II, not GRASE; and class III, deficient wellbeing information to help a positive GRASE assurance. Presently, sunscreen producers are working with the FDA to talk about security information required for 8 of the 12 dynamic fixings recorded in classification III [1].

Dermatologists assume a critical part in instructing people in general about sunscreens and have made staggering advances in treating skin tumors, particularly melanomas. Be that as it may, the predominance and death rates related with skin malignancies keeps on climbing. As indicated in the paper it is important to "give objective and refreshed data on sunscreens." To date the primary wellspring of sunscreen instruction to dermatologists has come from the sunscreen business who have a multibillion-dollar interest in sunscreens.

Over the most recent couple of years there has been a surge of logical papers taking a gander at the security and viability of these items which has set off the FDA to eliminate 14 natural sunscreens from the Generally Recognized As Safe and Effective for human use class. So, there is a fantastic need to foster new dynamic fixings, yet in addition to foster models that will completely demonstrate that these fixings are powerful against skin tumors. To date there are no models accessible to decide basal cell carcinoma or melanoma hindrance; there are a few models in mice that gander at cutaneous squamous cell carcinoma anticipation, yet they ought to likewise be approved [2].

Ultimately, it very well may be profitable if dermatology diaries like JAMA and AAD would be more comprehensive permitting researchers, not related with the business, to distribute. This maybe would give dermatologists extra wellsprings of data that could be useful in teaching purchasers in front of magazine and media sources, limiting disarray to all.

Use of suncreening agents is beneficial in minimizing the occurrence of skin cancers in people with fair skin. However, the same effect on Asian skin is debatable, as this skin type is considered to be resistant to skin cancers. Sunscreen use is advisable in young adults to prevent and minimize other photodamaging effects. Affordability and proper application techniques are the challenges that must be addressed in order to achieve regular sunscreen usage. The authors recommend further comparative studies on sunscreens as well as studies on the Indian population, as there is insufficient data in this population [3].
